

CHAPTER 11 HEATING - HYDRONIC SYSTEM SIZING

11.2 Expansion Tank

Expansion Tank Sizing

The expansion tank accommodates expansion in volume of the water in a hydronic system (see section 11.1) due to change of temperature (about 70 -80 degC), i.e. it provides the space into which the noncompressible liquid expands. The preferred location for the expansion tank is after the boiler/heater but before the pump to decrease the risk of cavitation at the pump inlet due to low pressure. The volume required for the expansion tank (generally closed type) is a function of the difference in system water volume due to the change in temperature and pressure (ASHRAE, 1996).

Example: Consider selection of an expansion tank for a hydronic heating system serving an apartment in the fifth floor of a 5-story high building. Assume that the boiler, located on the ground floor, is connected to the radiator system with a reverse return system.

First estimate total system volume:

Piping estimate (assume reverse return system):

$$r := 14 \text{ mm} \quad h := 15 \text{ m}$$

$$V_p := \pi \cdot r^2 \cdot h \cdot 4 \quad V_p = 0.037 \text{ m}^3 \quad \text{volume of water in pipes}$$

$$V_b := 25 \text{ liter} \quad \text{water in boiler}$$

Estimate of water in radiators (total output 14 Kw). It is assumed that the radiator length is approximately 1 m per 1160 watts and that it holds 4.2 liters per meter of length:

$$Q_{aux} := 14000 \text{ watt} \quad L_{rad} := Q_{aux} \frac{\text{m}}{1160 \text{ watt}} \quad V_r := L_{rad} \cdot 4.2 \frac{\text{liter}}{\text{m}}$$

$$V_r = 50.69 \text{ liter}$$

System volume:

$$V_s := V_p + V_b + V_r \quad V_s = 112.635 \text{ liter}$$

Now consider change of volume between cold (1) and hot (2) conditions (see [section 8.2](#)):

$$v_1 := .0010007 \frac{m^3}{kg} \quad \text{spec. vol. of water at 14 degC}$$

$$v_2 := .0010361 \frac{m^3}{kg} \quad \text{spec. vol. of water at 90 degC}$$

$$\rho := 1000 \frac{kg}{m^3} \quad P_1 := \rho \cdot g \cdot h + 101000 \text{ Pa}$$

$$P_1 = (2.481 \cdot 10^5) \text{ Pa} \quad \text{pressure at low temperature}$$

$$P_2 := 400000 \text{ Pa} \quad \text{pressure at high temperature} \quad dT := 60 \text{ K}$$

$$\frac{v_2}{v_1} = 1.035 \quad \alpha := \frac{17.1 \cdot 10^{-6}}{K} \quad \text{expansion coefficient for pipes}$$

$$Vt := V_s \cdot \frac{\frac{v_2}{v_1} - 1 - 3 \cdot \alpha \cdot dT}{1 - \frac{P_1}{P_2}} \quad Vt = 9.579 \text{ liter} \quad \text{diaphragm type expansion tank}$$

$$Vt := V_s \cdot \frac{\frac{v_2}{v_1} - 1}{\frac{101000 \text{ Pa}}{P_1} - \frac{101000 \text{ Pa}}{P_2}} \quad Vt = 25.774 \text{ liter} \quad \text{closed expansion tank without diaphragm (neglecting pipe expansion)}$$
